# 1 INTRODUCTION

## 1.1 Scope

Stroma Built Environment Ltd has been commissioned to undertake an air quality assessment based on the potential impacts of existing and future traffic levels on a proposed development at Kingston Bridge House in the London Borough of Richmond upon Thames. The pollutants modelled as part of this assessment are nitrogen oxides (NO<sub>x</sub>) and particulate matter (PM<sub>10</sub>).

The impacts of vehicle emissions have been assessed using the techniques detailed within Volume 11, Section 3 of the Design Manual for Roads and Bridges (DMRB)<sup>1</sup>, the Local Air Quality Management Technical Guidance (LAQM.TG16)<sup>2</sup> and the London Local Air Quality Management Technical Guidance (LLAQM, TG19). The impact of road traffic emissions will be assessed using the ADMS-Roads air dispersion model. This model has been devised by Cambridge Environmental Research Consultants (CERC) and is described as a “comprehensive tool for investigating air pollution problems due to small networks of roads”.

It should be noted that the short-term impacts of NO<sub>2</sub> and PM<sub>10</sub> emissions have not been modelled as dispersion models are inevitably poor at predicting short-term peaks in pollutant concentrations, which are highly variable from year to year, and from site to site. Notwithstanding this, general assumptions have been made about short term concentrations based on the modelled annual mean concentrations.

An assessment on the potential impact on local air quality from demolition and construction activities at the site has not been undertaken as a full dataset wasn't available.

An Air Quality Neutral assessment for the transport emissions has been undertaken in accordance with the London Plan however a building emissions assessment has not been undertaken as it does not meet the criteria. .

## 1.2 Site Description

The proposed development site is located at Kingston Bridge House on the corner of Hampton Court Road and Church Grove. The proposed development is the recommissioning of the existing building to 89 residential units. A location plan can be found in figure 1.

**Figure 1 –Site Location Plan**

## 2 POLLUTANTS & LEGISLATION

### 2.1 Pollutant Overview

In most urban areas of the UK, traffic generated pollutants have become the most common pollutants. These are nitrogen dioxide (NO<sub>2</sub>), fine particulates (PM<sub>10</sub>), carbon monoxide (CO), 1,3-butadiene and benzene, as well as carbon dioxide (CO<sub>2</sub>). This air quality assessment focuses on NO<sub>2</sub> and PM<sub>10</sub>, as these pollutants are least likely to meet their Air Quality Strategy objectives near roads. Table 1 provides an overview of NO<sub>2</sub> and PM<sub>10</sub>.

**Table 1 – Overview of NO<sub>2</sub> and PM<sub>10</sub>**

Pollutant	Properties	Anthropogenic Sources	Natural Sources	Potential Effects
<b>Particles (PM<sub>10</sub>)</b>	Tiny particulates of solid or liquid nature suspended in the air	Road transport; Power generation plants; Production processes e.g. windblown dust	Soil erosion; Volcanoes; Forest fires; Sea salt crystals	Asthma; Lung cancer; Cardiovascular problems
<b>Nitrogen Dioxide (NO<sub>2</sub>)</b>	Reddish-brown coloured gas with a distinct odour	Road transport; Power generation plants; Fossil fuels – extraction & distribution; Petroleum refining	No natural sources, although nitric oxide (NO) can form in soils	Pulmonary edema; Various environmental impacts e.g. acid rain

### 2.2 Air Quality Strategy

The UK Government and the devolved administrations published the latest Air Quality Strategy for England, Scotland, Wales and Northern Ireland on 17 July 2007<sup>3</sup>. The Strategy provides an over-arching strategic framework for air quality management in the UK.

With regards to this assessment, the Air Quality Strategy contains national air quality standards and objectives established by the Government to protect human health. The objectives for nitrogen dioxide and particulates (PM<sub>10</sub> and PM<sub>2.5</sub>) have been set, along with seven other pollutants (benzene, 1,3-butadiene, carbon monoxide, lead, PAHs, sulphur dioxide and ozone). Those which are limit values required by EU Daughter Directives on Air Quality have been transposed into UK law through the Air Quality Standards Regulations 2010 which came into force on 11th June 2010. Table 2 provides the UK Air Quality Objectives for NO<sub>2</sub> and PM<sub>10</sub>.

**Table 2 – UK Air Quality Objectives for Nitrogen Dioxide and Particulate Matter**

Pollutant	Objective	Concentration measured as
<b>Nitrogen Dioxide (NO<sub>2</sub>)</b>	200µg/m <sup>3</sup> not to be exceeded more than 18 times a year	1 hour mean
	40µg/m <sup>3</sup>	Annual mean
<b>Particles (PM<sub>10</sub>)</b>	50µg/m <sup>3</sup> not to be exceeded more than 35 times a year	24 hour mean

<sup>3</sup> The Air Quality Strategy for England, Scotland, Wales and Northern Ireland, Department for Environment, Food and Rural Affairs in partnership with the Scottish Executive, Welsh Assembly Government and Department of the Environment Northern Ireland, July 2007

	40µg/m <sup>3</sup>	Annual mean
<b>Particles (PM<sub>2.5</sub>)</b>	25µg/m <sup>3</sup> (except Scotland)	Annual Mean

Objectives for PM<sub>2.5</sub> were also introduced by the UK Government and the Devolved Administrations in 2010. However, these are not included in Regulations as the Air Quality Strategy has adopted an “exposure reduction” approach for PM<sub>2.5</sub> in order to seek a more efficient way of achieving further reductions in the health effects of air pollution by providing a driver to improve air quality everywhere in the UK rather than just in a small number of localised hotspot areas.

As defined in Table 4, background PM<sub>2.5</sub> concentrations are well below the limit value of 25 µg/m<sup>3</sup>. As such, no further consideration has been given to PM<sub>2.5</sub> within this assessment.

### **2.3 London Local Air Quality Management (LLAQM)**

At the core of LLAQM delivery are three pollutant objectives; these are: nitrogen dioxide (NO<sub>2</sub>), particulate matter (PM<sub>10</sub>) and sulphur dioxide (SO<sub>2</sub>). All current Air Quality Management Areas (AQMA) across the UK are declared for one or more of these pollutants, with NO<sub>2</sub> accounting for the majority. It is a statutory requirement for local authorities to regularly review and assess air quality in their area and take action to improve air quality when objectives set out in regulation cannot be met.

#### **2.3.1 The London Borough of Richmond upon Thames**

The Council has declared an Air Quality Management Area (AQMA). The AQMA has been declared for the Annual Mean of NO<sub>2</sub> and 24-Hour and Annual Mean of PM<sub>10</sub>. Furthermore, the AQMA covers the entire borough and as such the proposed development lies within this AQMA.

There are currently 187 Air Quality Focus areas which have been declared across the 33 London Boroughs. The proposed development lies outside the Kingston Bridge/Kingston Street focus area.

## **3 PLANNING POLICY & GUIDANCE**

### **3.1 National Planning Policy & Guidance**

#### **3.1.1 National Planning Policy Framework**

On a national level, air quality can be a material consideration in planning decisions. The National Planning Policy Framework (NPPF)<sup>4</sup> for England, revised and released on 19<sup>th</sup> February 2019, is considered a key part of the Governments reforms to make the planning system less complex and more accessible, to protect the environment and to promote sustainable growth. The NPPF replaces the Planning Policy Statement 23 (PPS23) Planning and Pollution Control<sup>5</sup>.

Paragraph 170 within the NPPF states that “planning policies and decisions should contribute to and enhance the natural and local environment” and that developments “should, wherever possible, help to improve local environmental conditions such as air and water quality, taking into account relevant information such as river basin management plans”

It goes on to state in paragraph 181 that “planning policies and decisions should sustain and contribute towards compliance with relevant limit values or national objectives for pollutants, taking into account the presence of Air Quality Management Areas and Clean Air Zones, and the cumulative impacts from individual sites in local areas. Opportunities to improve air quality or mitigate impacts should be identified, such as through traffic and travel management, and green infrastructure provision and enhancement. So far as possible these opportunities should be considered at the plan-making stage, to ensure a strategic approach and limit the need for issues to be reconsidered when determining individual applications. Planning decisions should ensure that any new development in Air Quality Management Areas and Clean Air Zones is consistent with the local air quality action plan”.

#### **3.1.2 Land-Use Planning & Development Control**

In January 2017, Environmental Protection UK (EPUK) and the Institute of Air Quality Management (IAQM) produced guidance to ensure that air quality is adequately considered in the land-use planning and development control processes<sup>6</sup>.

The guidance document is particularly applicable to assessing the effect of changes in exposure of members of the public resulting from residential and mixed-use developments, especially those within urban areas where air quality is poorer. It is also relevant to other forms of development where a proposal could affect local air quality and for which no other guidance exists.

## 3.2 Regional Planning Policy

### 3.2.1 The Mayor's Air Quality Strategy

In October 2010, the Mayor's Air Quality Strategy<sup>7</sup> was released. The strategy sets out a framework for delivering improvements to London's air quality and includes measures aimed at reducing emissions from transport, homes, offices and new developments, as well as raising awareness of air quality issues and its impact on health.

### 3.2.2 The London Plan

In March 2016, the updated London Plan was published by the Greater London Authority<sup>8</sup>. The London Plan provides an overall strategic plan for London, setting out an integrated economic, environmental, transport and social framework for the development of London over the next 20–25 years. The Plan brings together the geographic and locational aspects of the Mayor's other strategies, including a range of environmental issues such as climate change (adaptation and mitigation), air quality, noise and waste.

Policy 7.14 relates specifically to improving air quality and states the following:

*"The Mayor recognises the importance of tackling air pollution and improving air quality to London's development and the health and well-being of its people. He will work with strategic partners to ensure that the spatial, climate change, transport and design policies of this plan support implementation of his Air Quality and Transport strategies to achieve reductions in pollutant emissions and minimize public exposure to pollution".*

It goes on to state the following with regards to planning decisions:

*"Development proposals should:*

- a minimise increased exposure to existing poor air quality and make provision to address local problems of air quality (particularly within Air Quality Management Areas (AQMAs) and where development is likely to be used by large numbers of those particularly vulnerable to poor air quality, such as children or older people) such as by design solutions, buffer zones or steps to promote greater use of sustainable transport modes through travel plans (see Policy 6.3)*
- b promote sustainable design and construction to reduce emissions from the demolition and construction of buildings following the best practice guidance in the GLA and London Councils' 'The control of dust and emissions from construction and demolition'*
- c be at least 'air quality neutral' and not lead to further deterioration of existing poor air quality (such as areas designated as Air Quality Management Areas (AQMAs)).*
- d ensure that where provision needs to be made to reduce emissions from a development, this is usually made on-site. Where it can be demonstrated that on-site provision is impractical or inappropriate, and that it is possible to put in place measures having clearly demonstrated equivalent air quality benefits, planning obligations or planning conditions should be used as appropriate to ensure this, whether on a scheme by scheme basis or through joint area-based approaches*
- e where the development requires a detailed air quality assessment and biomass boilers are included, the assessment should forecast pollutant concentrations. Permission*

---

<sup>7</sup> Clearing the Air: The Mayor's Air Quality Strategy. October 2010

<sup>8</sup> The London Plan. The Spatial Development Strategy for London. Consolidated with Alterations. March 2016

*should only be granted if no adverse air quality impacts from the biomass boiler are identified”.*

## 4 ASSESSMENT METHODOLOGY

### 4.1 Operational Phase (Traffic Emissions)

#### 4.1.1 Modelled Scenarios

A modelled baseline year of 2019 has been used as this corresponds with the latest year of monitoring undertaken by the Council. The future year has also been chosen (2023) representing the first full year with the proposed development in place. Two scenarios have been adopted as part of the assessment. These are as follows:

- **Scenario 1** – existing levels of air quality / model verification (2019); and
- **Scenario 2** – future impact of traffic emissions on the proposed development i.e. introduction of new exposure (2023)

Predicted concentrations will be compared to the Air Quality Strategy objectives. Background pollutant concentrations and vehicle emission rates for all modelled years are based on the latest data issued by Defra. These background concentrations and emission factors are discussed further in the following sections.

#### 4.1.2 ADMS-Roads

Modelling the impact of traffic emissions on the proposed development will be undertaken using the latest version of the ADMS-Roads model<sup>9</sup>. ADMS-Roads is significantly more advanced than that of most other air dispersion models in that it incorporates the latest understanding of the boundary layer structure, and goes beyond the simplistic Pasquill-Gifford stability categories method with explicit calculation of important parameters. The model uses advanced algorithms for the height-dependence of wind speed, turbulence and stability to produce improved predictions.

#### 4.1.3 Emission Factors

Defra and the Devolved Administrations have provided an updated Emission Factors Toolkit (Version 10.1) which incorporates updated NO<sub>x</sub> emissions factors and vehicle fleet information<sup>10</sup>. These emission factors have been integrated into the latest ADMS-Roads modelling software. However, in order to undertake a worst-case assessment emission factors for 2019 have been used for all modelled years.

#### 4.1.4 Traffic Data

Baseline flows along the local roads are available from the London Atmospheric Emissions Inventory (LAEI)<sup>11</sup>. Baseline (2016) data from the LAEI has been projected to 2019 and 2023. Projection of traffic data has been undertaken using growth factors specific to the local authority, obtained from TEMPro<sup>12</sup>. The projected flow rates are provided in Table 3. It is assumed that the percentage HDV and speed will remain unchanged in future years.

Where a link approaches a junction a speed of 20 kph has been modelled in order to represent queuing traffic at a junction. This is the approach recommended by LLAQM.

<sup>10</sup> [https://laqm.defra.gov.uk/documents/EFT2020\\_v10.1.xlsb](https://laqm.defra.gov.uk/documents/EFT2020_v10.1.xlsb)

<sup>11</sup> <https://data.london.gov.uk/dataset/london-atmospheric-emissions-inventory-2016>

<sup>12</sup> TEMPro (Trip End Model Presentation Program) version 7. Department for Transport

**Table 3 – Annual Average Daily Traffic Flows, Percentage HDV and Speeds for Modelled Roads**

Link Name	Baseline AADT 2018	Future Baseline AADT 2021	HDV (%)	Speed (kph)
Hampton Court Road	18,240	18,965	6.5	17
Church Grove	25,637	26,657	3.6	31

## 4.2 Background Concentrations

Background NO<sub>x</sub>, NO<sub>2</sub> and PM<sub>10</sub> concentrations have been obtained from Defra<sup>13</sup>. These 1 km x 1 km grid resolution maps are derived from a base year of 2018 (for NO<sub>x</sub>, NO<sub>2</sub>, PM<sub>10</sub> and PM<sub>2.5</sub> only), which are then projected to future years up to 2030. Background concentrations of NO<sub>2</sub>, PM<sub>10</sub> and PM<sub>2.5</sub> derived from Defra are provided in Table 4.

**Table 4 – Background NO<sub>x</sub>, NO<sub>2</sub>, PM<sub>10</sub> and PM<sub>2.5</sub> Concentrations**

Location	Pollutant	X	Y	2019
Proposed Development	NO <sub>2</sub>	517500	169500	21.1
	NO <sub>x</sub>			30.7
	PM <sub>10</sub>			16.2
	PM <sub>2.5</sub>			11.0

In order to undertake a worst-case assessment, 2019 background concentrations have been assumed for all modelled scenarios.

## 4.3 Surface Roughness

A surface roughness of 1.5 metres has been used in the model. This value is provided by ADMS-Roads as a typical roughness length for large urban areas. This value has been used across the modelled domain.

## 4.4 Meteorological Data

Hourly sequential meteorological data from the London Heathrow Airport meteorological station has been used. Wind speed and direction data from the London Heathrow Airport meteorological station has been plotted as a wind rose in Figure 2.

<sup>13</sup> <https://uk-air.defra.gov.uk/data/laqm-background-maps?year=2018>

Figure 2 – Wind Speed and Direction Data, London Heathrow Airport (2019)

## 4.5 Model Output

### 4.5.1 NO<sub>x</sub>/NO<sub>2</sub> Relationship

Following recent evidence that shows the proportion of primary NO<sub>2</sub> in vehicle exhaust has increased<sup>14</sup>. As such, a new NO<sub>x</sub> to NO<sub>2</sub> calculator has been devised<sup>15</sup>. This new calculator has been used to determine NO<sub>2</sub> concentrations for this assessment, based on predicted NO<sub>x</sub> concentrations using ADMS-Roads. Converted NO<sub>2</sub> concentrations are initially compared to local monitoring data in order to verify the model output. If the model performance is considered unacceptable then the NO<sub>x</sub> concentrations are adjusted before conversion to NO<sub>2</sub>.

<sup>14</sup> Trends in Primary Nitrogen Dioxide in the UK, Air Quality Expert Group, 2007

<sup>15</sup> [http://laqm.defra.gov.uk/documents/no2tonox9\\_ja-forweb\\_june2016.xls](http://laqm.defra.gov.uk/documents/no2tonox9_ja-forweb_june2016.xls)

## 4.5.2 Predicted Short Term Concentrations

As discussed in the introduction, it has not been possible to model the short-term impacts of NO<sub>2</sub> and PM<sub>10</sub>. Research undertaken in 2003<sup>16</sup> has indicated that the hourly NO<sub>2</sub> objective is unlikely to be exceeded at a roadside location where the annual mean NO<sub>2</sub> concentration is less than 60 µg/m<sup>3</sup>.

For PM<sub>10</sub>, a relationship between the annual mean and the number of 24-hour mean exceedances has been devised and is as follows:

- No. 24-hour mean exceedances =  $-18.5 + 0.00145 \times \text{annual mean}^3 + (206/\text{annual mean})$

This relationship has been applied to the modelled annual mean concentrations in order to estimate the number of 24-hourly exceedances.

## 4.5.3 Model Verification

The monitoring sites listed in Table 5 has been used for the purposes of model verification. These are the closest monitoring sites to the proposed development.

**Table 5 – Modelled Verification Locations**

Site ID	X	Y	Height (m)
KT5*	518576	169503	1.6
35**	517524	169583	2.2

\*The London Borough of Kingston upon Thames  
 \*\*The London Borough of Richmond upon Thames

## 4.5.4 Receptor Locations

In order to meet the requirements of planning condition 21, a 128m X 112m grid consisting of 1,328 individual points have been modelled. These are interpolated into contour plots which can then overlay the site plan to ascertain the air quality concentrations across the development.

## 4.6 Significance Criteria

### 4.6.1 Operational Phase

The significance of emissions will be determined by comparing the predicted results to the Air Pollution Exposure Criteria (APEC) detailed in the Air Quality and Planning Guidance written by the London Air Pollution Planning and the Local Environment (APPLE) working group. The Air Pollution Exposure Criteria is considered appropriate to describe the significance of the impacts predicted, together with an indication as to the level of mitigation required in order for the development to be approved. The APEC table is provided below.

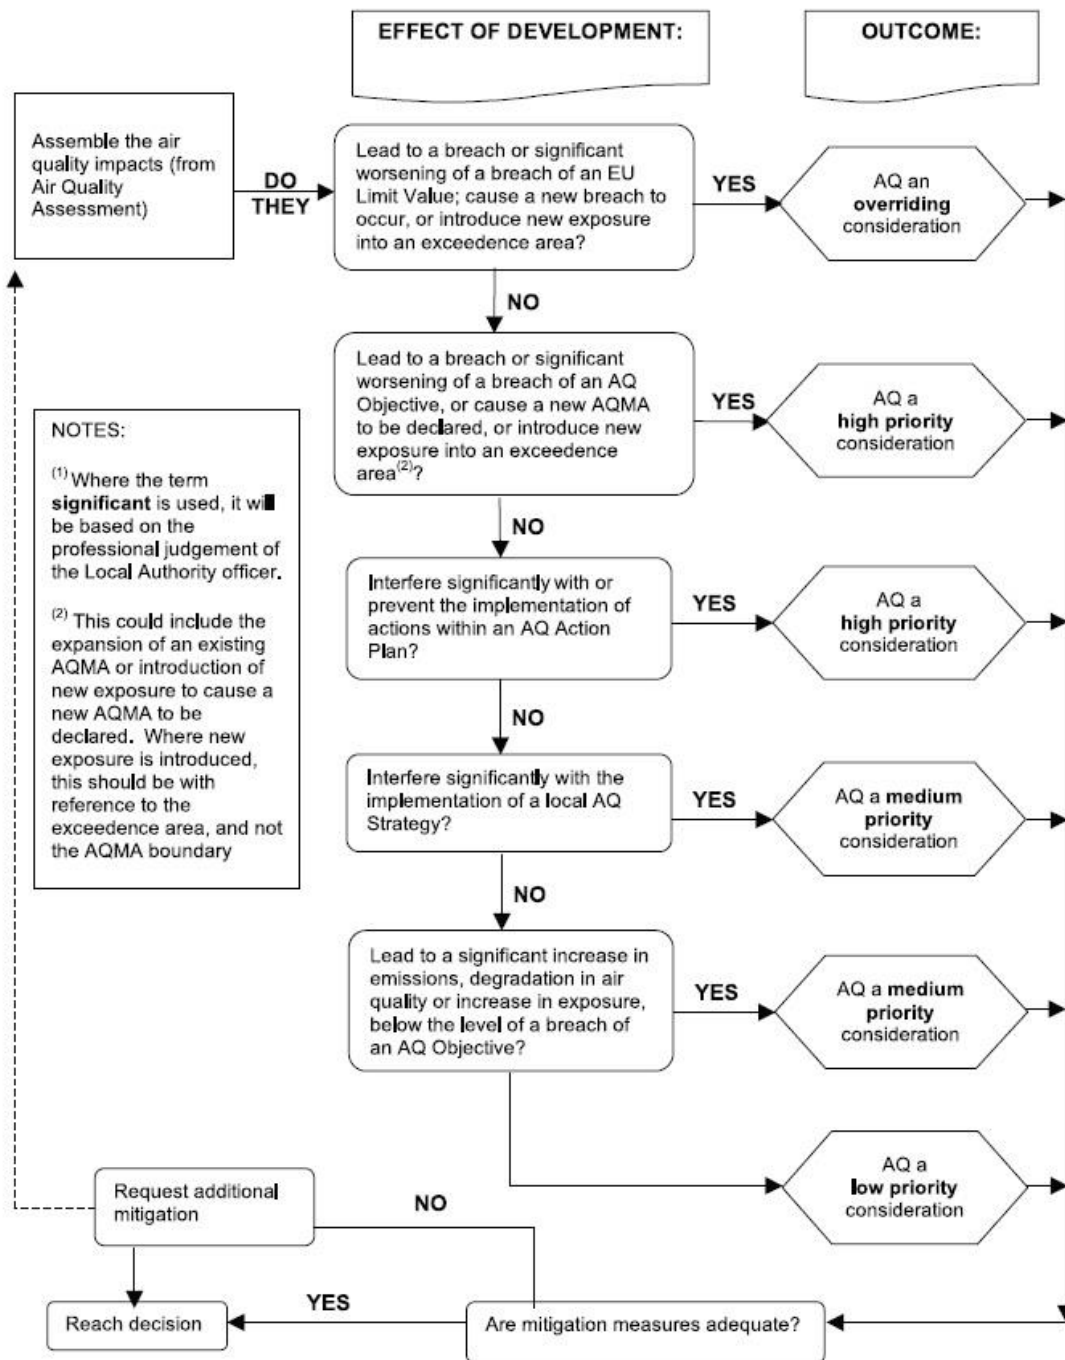

**Table 6 – Air Pollution Exposure Criteria (APEC)**

APEC Category	NO <sub>2</sub>	PM <sub>10</sub>	Recommendations
A	>5% below national annual mean objective	>5% below national annual mean objective >1-day less than national 24-hour objective	No air quality grounds for refusal; however mitigation of any emissions should be considered.

<sup>16</sup> Analysis of Relationship between 1-Hour and Annual Mean Nitrogen Dioxide at UK Roadside and Kerbside Monitoring Sites, Laxen and Marnar, 2003

<b>B</b>	Between 5% below or above national annual mean objective	Between 5% above or below national annual mean objective Between 1-day above or below national 24-hour objective	May not be sufficient air quality grounds for refusal, however appropriate mitigation must be considered
<b>C</b>	>5% above national annual mean objective	>5% above national annual mean objective >1-day more than national 24-hour objective	Refusal on air quality grounds should be anticipated, unless the Local Authority has a specific policy enabling such land use and ensure best endeavours to reduce exposure are incorporated

**Figure 3 – Assessing the Significance of Air Quality Impacts of a Development Proposal**

## 5 AIR QUALITY ASSESSMENT

### 5.1 Impact of Vehicle Emissions

#### 5.1.1 Model Verification

Using the guidance provided within the London Local Air Quality Management Technical Guidance TG(19), the modelled output has been verified against the monitoring data obtained from the site listed in Table 7. The following tables provide a summary of the model verification process for NO<sub>x</sub>/NO<sub>2</sub> and PM<sub>10</sub> concentrations.

**Table 7 – Comparison of Modelled and Monitored NO<sub>2</sub> and PM<sub>10</sub> Concentrations (µg/m<sup>3</sup>)**

Verification Location	Modelled Concentration	Monitored Concentration	Difference [(modelled - monitored)/monitored] x100
KT5	37.8	57.7	-34.5%
35	27.2	36.0	-24.5%

As described in the Technical Guidance (LLAQM.TG19), in order to provide more confidence in the model predictions and the decisions based on these, the majority of results should be within ±25% (ideally ±10%) of the monitored concentrations. In order to improve the confidence in modelled concentrations across the modelled domain the model output has been adjusted. This is described further in the next section.

#### 5.1.2 Model Adjustment

In order to undertake model adjustment, it is first necessary to derive the monitored and modelled road contributions of NO<sub>x</sub> (excluding background). The modelled road contribution NO<sub>x</sub> is taken directly from the ADMS-Roads output before it has been converted to NO<sub>2</sub> using the NO<sub>x</sub> to NO<sub>2</sub> calculator described in Section 4.6.1. The NO<sub>x</sub> to NO<sub>2</sub> calculator can also be used to derive monitored road contributions of NO<sub>x</sub> from NO<sub>2</sub> diffusion tube results. A summary of these calculations is provided in Table 8.

**Table 8 – Monitored NO<sub>x</sub> and NO<sub>2</sub> concentrations**

Verification Location	Monitored Total NO <sub>2</sub>	Defra Background NO <sub>2</sub>	Monitored road contribution NO <sub>2</sub> (total – background)	Monitored road contribution NO <sub>x</sub> (total – background)	Modelled road contribution NO <sub>x</sub> (excludes background)	Ratio of monitored road contribution NO <sub>x</sub> / modelled road contribution NO <sub>x</sub>
KT5	57.7	24.1	33.6	82.9	29.8	2.78
35	36.0	21.1	14.9	32.2	12.5	2.57

Once the monitored and modelled road contributions of NO<sub>x</sub> (excluding background) have been derived the contributions of NO<sub>x</sub> are compared and a ratio derived. In this case it is 2.677 and is used to adjust the modelled road contribution of NO<sub>x</sub>. This is shown in Table 9.

**Figure 4 – Linear Regression of Modelled and Monitored NO<sub>2</sub>**

**Table 9 – Adjustment of Modelled NO<sub>x</sub> Contributions**

Verification Location	Adjustment factor for modelled road contribution	Adjusted modelled road contribution NO <sub>x</sub>	Modelled total NO <sub>2</sub> (based on empirical NO <sub>x</sub> /NO <sub>2</sub> relationship)	Monitored total NO <sub>2</sub>	% Difference [(modelled – monitored) / monitored] x 100
JT5	2.677	79.9	56.7	57.7	-1.8%
35	2.677	33.4	36.5	36.0	1.5%

Following adjustment of the modelled NO<sub>x</sub> concentrations by a factor of 2.677 the total NO<sub>2</sub> concentration at the model verification location has been calculated using the method described in Section 4.6.1. The revised NO<sub>2</sub> concentration, shown in Table 9, indicates a more acceptable model performance when compared against the monitored NO<sub>2</sub> concentrations. As such, an adjustment factor of 2.677 has been applied to all modelled NO<sub>x</sub> concentrations across the model domain before conversion to NO<sub>2</sub>.

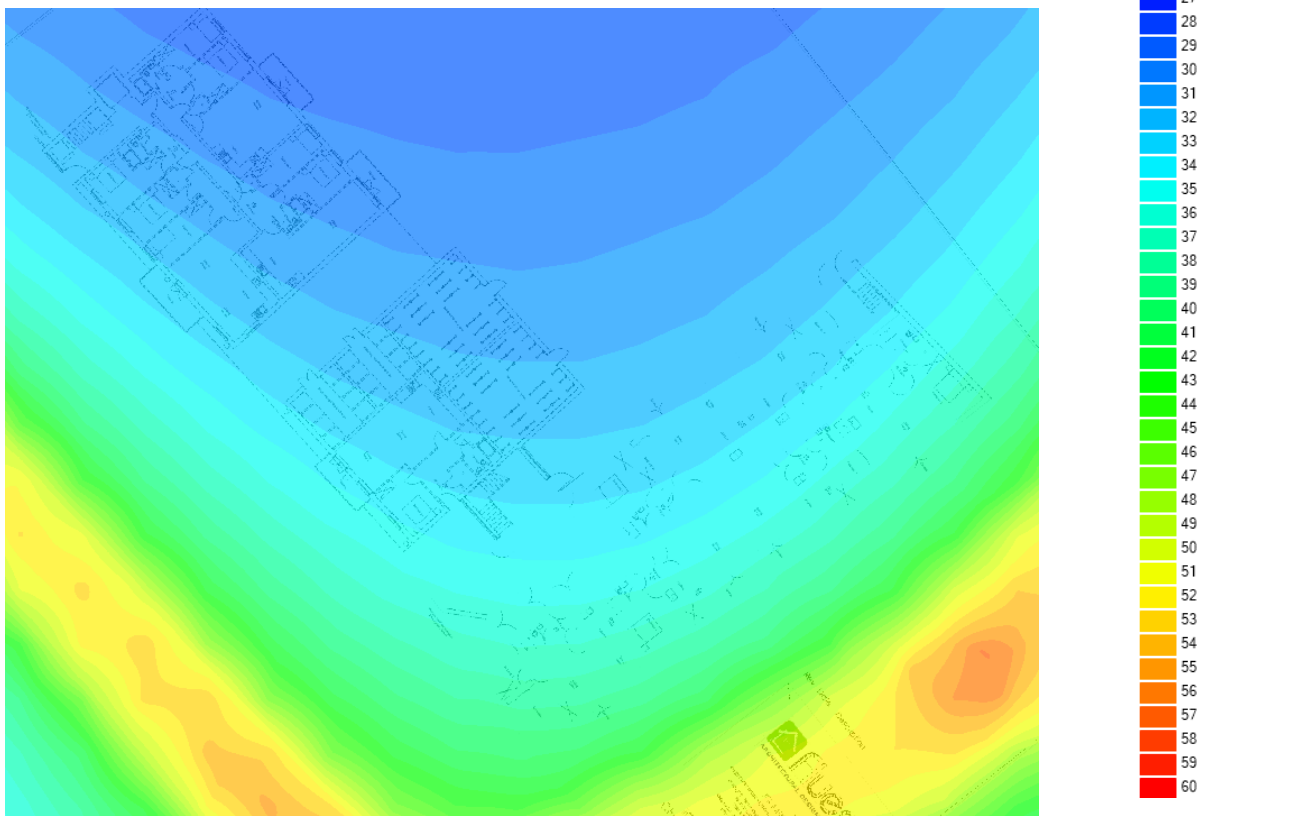

### 5.1.3 Nitrogen Dioxide

Predicted annual mean concentrations for NO<sub>2</sub> at the proposed development in 2019 and 2023 have been plotted in figures 5 to 6. As mentioned in Section 4.5.1, NO<sub>2</sub> concentrations have been calculated from the predicted NO<sub>x</sub> concentrations using the latest NO<sub>x</sub>-NO<sub>2</sub> conversion spreadsheet available from the Air Quality Archive.

**Figure 5 – Predicted 2019 NO<sub>2</sub> concentrations across the development**

**Figure 6 – Predicted 2023 NO<sub>2</sub> concentrations across the development**

The ADMS predictions for annual mean NO<sub>2</sub> concentrations in 2019 and 2023 indicate that the annual mean objective (40 µg/m<sup>3</sup>) would be achieved at the majority of the modelled receptor locations on all floors. However the receptors on the ground floor closest to Hampton Court Road are within + or - 5% of the annual mean objective and so it is possible they are above the objective.

Nitrogen dioxide also has an hourly objective of 200 µg/m<sup>3</sup> not to be exceeded more than 18 times in one year. However, the hourly mean concentration has not been calculated directly by ADMS Roads. This is as a result of an evaluation of continuous monitoring data from across the UK that revealed that the relationship between the annual mean and hourly mean NO<sub>2</sub> concentrations was very weak. Nonetheless, research undertaken in 2003<sup>17</sup> has indicated that the hourly NO<sub>2</sub> objective is unlikely to be exceeded at a roadside location where the annual mean NO<sub>2</sub> concentration is less than 60 µg/m<sup>3</sup>. Given that predicted NO<sub>2</sub> concentration in 2019 and 2023 are below 60 µg/m<sup>3</sup> at the modelled receptor locations, the likelihood of the short-term objective for NO<sub>2</sub> being exceeded is low.

#### 5.1.4 Particulate Matter

Predicted annual mean concentrations for PM<sub>10</sub> in 2019 and 2023 are provided in figures 7 and 8.

**Figure 7 – Predicted 2019 PM<sub>10</sub> concentrations across the development**

<sup>17</sup> Analysis of Relationship between 1-Hour and Annual Mean Nitrogen Dioxide at UK Roadside and Kerbside Monitoring Sites, Laxen and Marner, 2003

**Figure 8 – Predicted 2023 PM<sub>10</sub> concentrations across the development**

The ADMS predictions for annual mean PM<sub>10</sub> concentrations in 2019 and 2023 indicate that the annual mean objective (40 µg/m<sup>3</sup>) would be achieved at all the modelled receptor locations. In addition, the maximum number of days when PM<sub>10</sub> concentrations are more than 50 µg/m<sup>3</sup> is 11, less than the 35 exceedances allowed in the regulations.

## 6 AIR QUALITY NEUTRAL ASSESSMENT

### 6.1 Introduction

Policy 7.14 within the London Plan states that every “major” development in Greater London be at least “air quality neutral” and not lead to further deterioration of existing poor air quality. This definition comes from the Town and Country Planning Order<sup>18</sup>, to which the London Plan refers.

Within the London Plan, a “major” development is defined by the following criteria:

- 10 or more residential dwellings (or where the number is not given, an area of more than 0.5 ha); or
- For all other uses, where floor space is 1,000 sq m or more (or the site is 1 ha or more).

As such, the proposed development is classified as a “major” development in accordance with 1,000 sq m or more floor space.

<sup>18</sup> Town and Country Planning (Development Management Procedure)(England) Order, March 2015

The air quality neutral assessment has followed the methodology outlined in the Sustainable Design and Construction Supplementary Planning Guidance (SPG)<sup>19</sup> and the Air Quality Neutral Planning Support Update<sup>20</sup>. Within these documents, benchmarks have been provided in relation to building and transport emissions, together with a methodology for calculating the building related emissions for a particular development. The building and transport related emissions are then compared to the Building Emissions Benchmarks (BEBs) and Transport Emissions Benchmarks (TEBs) to determine whether the benchmarks are being exceeded. If so, then mitigation measures are required to reduce the site emissions, either by on-site measures or by off-setting.

## 6.2 Transport Emissions

As per the Air Quality Neutral Planning Update, the land use category applicable to the residential dwellings, has been used. The Transport Emissions Benchmarks (TEBs) are calculated by multiplying the relevant emission benchmarks by the number of dwellings. This is summarised in Table 10.

**Table 10 – Transport Emissions Benchmarks (NOx and PM<sub>10</sub>)**

NOx				
Land Use	No of Dwellings	Transport Emission Benchmark (g/dwelling/annum)	Transport Emissions (g/annum)	Transport Emissions (kg/annum)
C3	89	1553	138,217	138.2
<b>Total Benchmarked Transport NOx Emission</b>			<b>138,217</b>	<b>138.2</b>
PM <sub>10</sub>				
Land Use	No of Dwellings	Transport Emission Benchmark (g/dwelling/annum)	Transport Emissions (g/annum)	Transport Emissions (kg/annum)
C3	89	267	23,763	23.8
<b>Total Benchmarked Transport PM<sub>10</sub> Emission</b>			<b>23,763</b>	<b>23.8</b>

The proposed development will generate 71.7 daily vehicle movements (26,171 per annum) from the proposed residential use. As such, the total trip emissions for NOx and PM<sub>10</sub> have been calculated in Table 11.

**Table 11 – Total Transport Emissions (NOx and PM<sub>10</sub>)**

Land Use	Total Trips Per Annum	Total Distance (veh-km/annum)	Total Transport Emissions (g/annum)	Total Transport Emissions (kg/annum)
NOx				
C3	26,171	298,344	105,315	105.3
<b>Total Transport NOx Emission</b>			<b>105,315</b>	<b>105.3</b>
PM <sub>10</sub>				

<sup>19</sup> Sustainable Design and Construction Supplementary Planning Guidance (SPG), Mayor of London, April 2014

<sup>20</sup> Air Quality Neutral Planning Support Update: GLA 80371, April 2014

<b>C3</b>	26,171	298,344	18,080	18.1
<b>Total Transport PM<sub>10</sub> Emission</b>			18,080	18.1

Based on the comparison between the total transport emissions and Transport Emissions Benchmarks (see Table 12) the proposed development does meet the air quality neutral requirements.

**Table 12 – Comparison of Total Transport Emissions and Transport Emissions Benchmarks**

<b>Pollutant</b>	<b>Total Benchmarked Transport Emissions (kg/annum)</b>	<b>Total Transport Emissions (kg/annum)</b>	<b>Difference (kg/annum)</b>
<b>NOx</b>	<b>138.2</b>	<b>105.3</b>	<b>-32.9</b>
<b>PM<sub>10</sub></b>	<b>23.8</b>	<b>18.1</b>	<b>-5.7</b>

## **7 CONCLUSIONS AND RECOMMENDATIONS**

### **7.1 Impact of Vehicle Emissions**

The air quality assessment has been based on a number of conservative/worst case assumptions outlined in section 4. This aims to provide confidence in the overall outcomes of the assessment when determining its significance. The majority of predicted NO<sub>2</sub> and PM<sub>10</sub> concentrations at the proposed development fall within APEC Category A, which states that there are “No air quality grounds for refusal; however mitigation of any emissions should be considered”. As such it can be determined that the proposed locations of the air intake locations are in areas which are expected to be below the UK air quality objective limits for NO<sub>2</sub> and PM<sub>10</sub>. However the ground floor receptors closest to Hampton Court Road are within + or - 5% of the annual mean objective (APEC Category B).

### **7.2 Impact of Air Quality Neutral Assessment**

The Air Quality Neutral Building Assessment for the proposed development demonstrated that it is below the benchmark. As such, the development is considered air quality neutral in regards to transport emissions and therefore no further mitigation is required.
