St Clare Business Park – Hampton Hill

1 Introduction

1.1 This engineering note has been prepared in response to comments received from the LLFA regarding the proposed drainage strategy at the St Clare Business Park in Hampton Hill.

2 Proposed Runoff Rates

2.1 In response to the LLFA requesting surface water runoff rates to be restricted to a maximum of 2.0 l/s, we have been in discussions with pump suppliers who have advised that they do not recommend pumping surface water at a rate lower than 2.7 l/s for a situation such as this due to concerns over the potential long running times. The minimum discharge rate they have recommended is 2.7 l/s and to protect the pump set, a hydro-brake has been added upstream of the pump chamber. We have re-run the MicroDrainage calculations based upon a discharge rate of 2.7 l/s, which has resulted in a required increase in surface water attenuation of 74m³. To accommodate this, both of the below ground attenuation tanks will be increased in width by 0.5m. To summarise:

- Attenuation required at 5 l/s = 634m³
- Attenuation required at 2.7 l/s = 707m³
- Attenuation provided by increasing tank width by 0.5m = 713m³

2.2 Refer to Appendix A for an updated Drainage Strategy drawing and MicroDrainage calculations.

3 Existing Runoff Rates

3.1 Regarding the existing surface water flow rates, the majority of the site currently discharges to soakaway. However, approximately 240m² of surface water currently discharges unrestricted to the adopted surface water sewer in Windmill Road.

3.2 The existing unrestricted surface water runoff rates have been calculated using the Modified Rational Method with rainfall intensity from Microdrainage Windes for a storm of 30 minutes' duration:

- $Q = 2.78 \times C_v \times CR \times A \times i$

Where:

- Q = Flow (l/s)
- CR = Routing coefficient = 1.3
- C_v = Coefficient of runoff = 0.9
- A = Area drained (hectares) = 0.024
- i = Rainfall intensity (mm/hr) (determined from Microdrainage Windes)

3.3 Based upon the above:

- 1-year Return Period = 1.75 l/s) where $i = 22.4$ mm/hr)
- 30-year Return Period = 4.3 l/s where $i = 55.5$ mm/hr)
- 100-year Return Period = 5.76 l/s where $i = 73.8$ mm/hr)

3.4 It is recognised that with a restricted flow rate of 2.7 l/s there may be a nominal increase in flows during the low intensity rainfall events. However, for the more onerous storms there will be a betterment which should reduce the risk of sewer flooding downstream of the site.

3.5 A Pre-Development Enquiry application was not previously made to Thames Water; though, Thames were a consultee of the planning application and as far as we are aware they have made no objections to the drainage proposals based upon the 5.0 l/s surface water discharge rate.

4 Groundwater Flooding

4.1 With regard to the risk of groundwater flooding, the detailed ground investigation report advised that the anticipated depth to the groundwater table is in the order of 2m to 3m below ground level, coincidental with the occurrence of the granular Taplow gravel formation. The report goes on to say ...*'Shallow groundwater on the site is anticipated to flow westward towards the unconfined soils of the abounding railway cutting or more regionally southwards towards the Longford River (<100m south), a tributary to the river Thames located 1.5km south of the subject site. Shallow and localised perched water is anticipated to be present in the underlying made ground. The presence of low permeability clay at relatively shallow depths beneath the site, while restricting downwards migration, may increase the potential for lateral migration of shallow groundwater.'*

4.2 Intrusive investigations established that below a depth of made ground (1.5m to 3.5m thick) the natural geology is gravels (1.5-3.5m bgl.), over London Clay. Groundwater levels recorded across the site varied between 1.3m and 3.5m below the existing ground level, which combined with the variable ground suggests that there is perched groundwater on the site.

4.3 Ground levels of the adjacent railway cutting (to the west) are significantly lower and as a result it is anticipated that the cutting is likely to have a significant impact on the natural groundwater levels within the site.

4.4 The basement is to be constructed in open cut with reinforced concrete walls and slabs, where piled foundations are to be provided to support the building. The basement is approximately 50mx47m which is cut into the slope, retaining in the order of 3.0m to the east and 1.5m to the west (adjacent to the railway). To mitigate the risk of groundwater flooding to the new building, the basement will be constructed using water resistant measures (such waterproof concrete) to form a watertight structure which will prevent groundwater entering the basement.

4.5 Network Rail have advised that there is a history of flooding within the railway cutting. Drainage investigations has established that the majority of site (7800m²) currently discharges surface water via soakaways, which is likely to be contributing to the flooding of the railway cutting. Due to the potential contamination issues associated with the made ground and concerns of flooding within the adjacent railway cutting, the surface water from the new development will discharge to surface water sewers rather than soakaways.

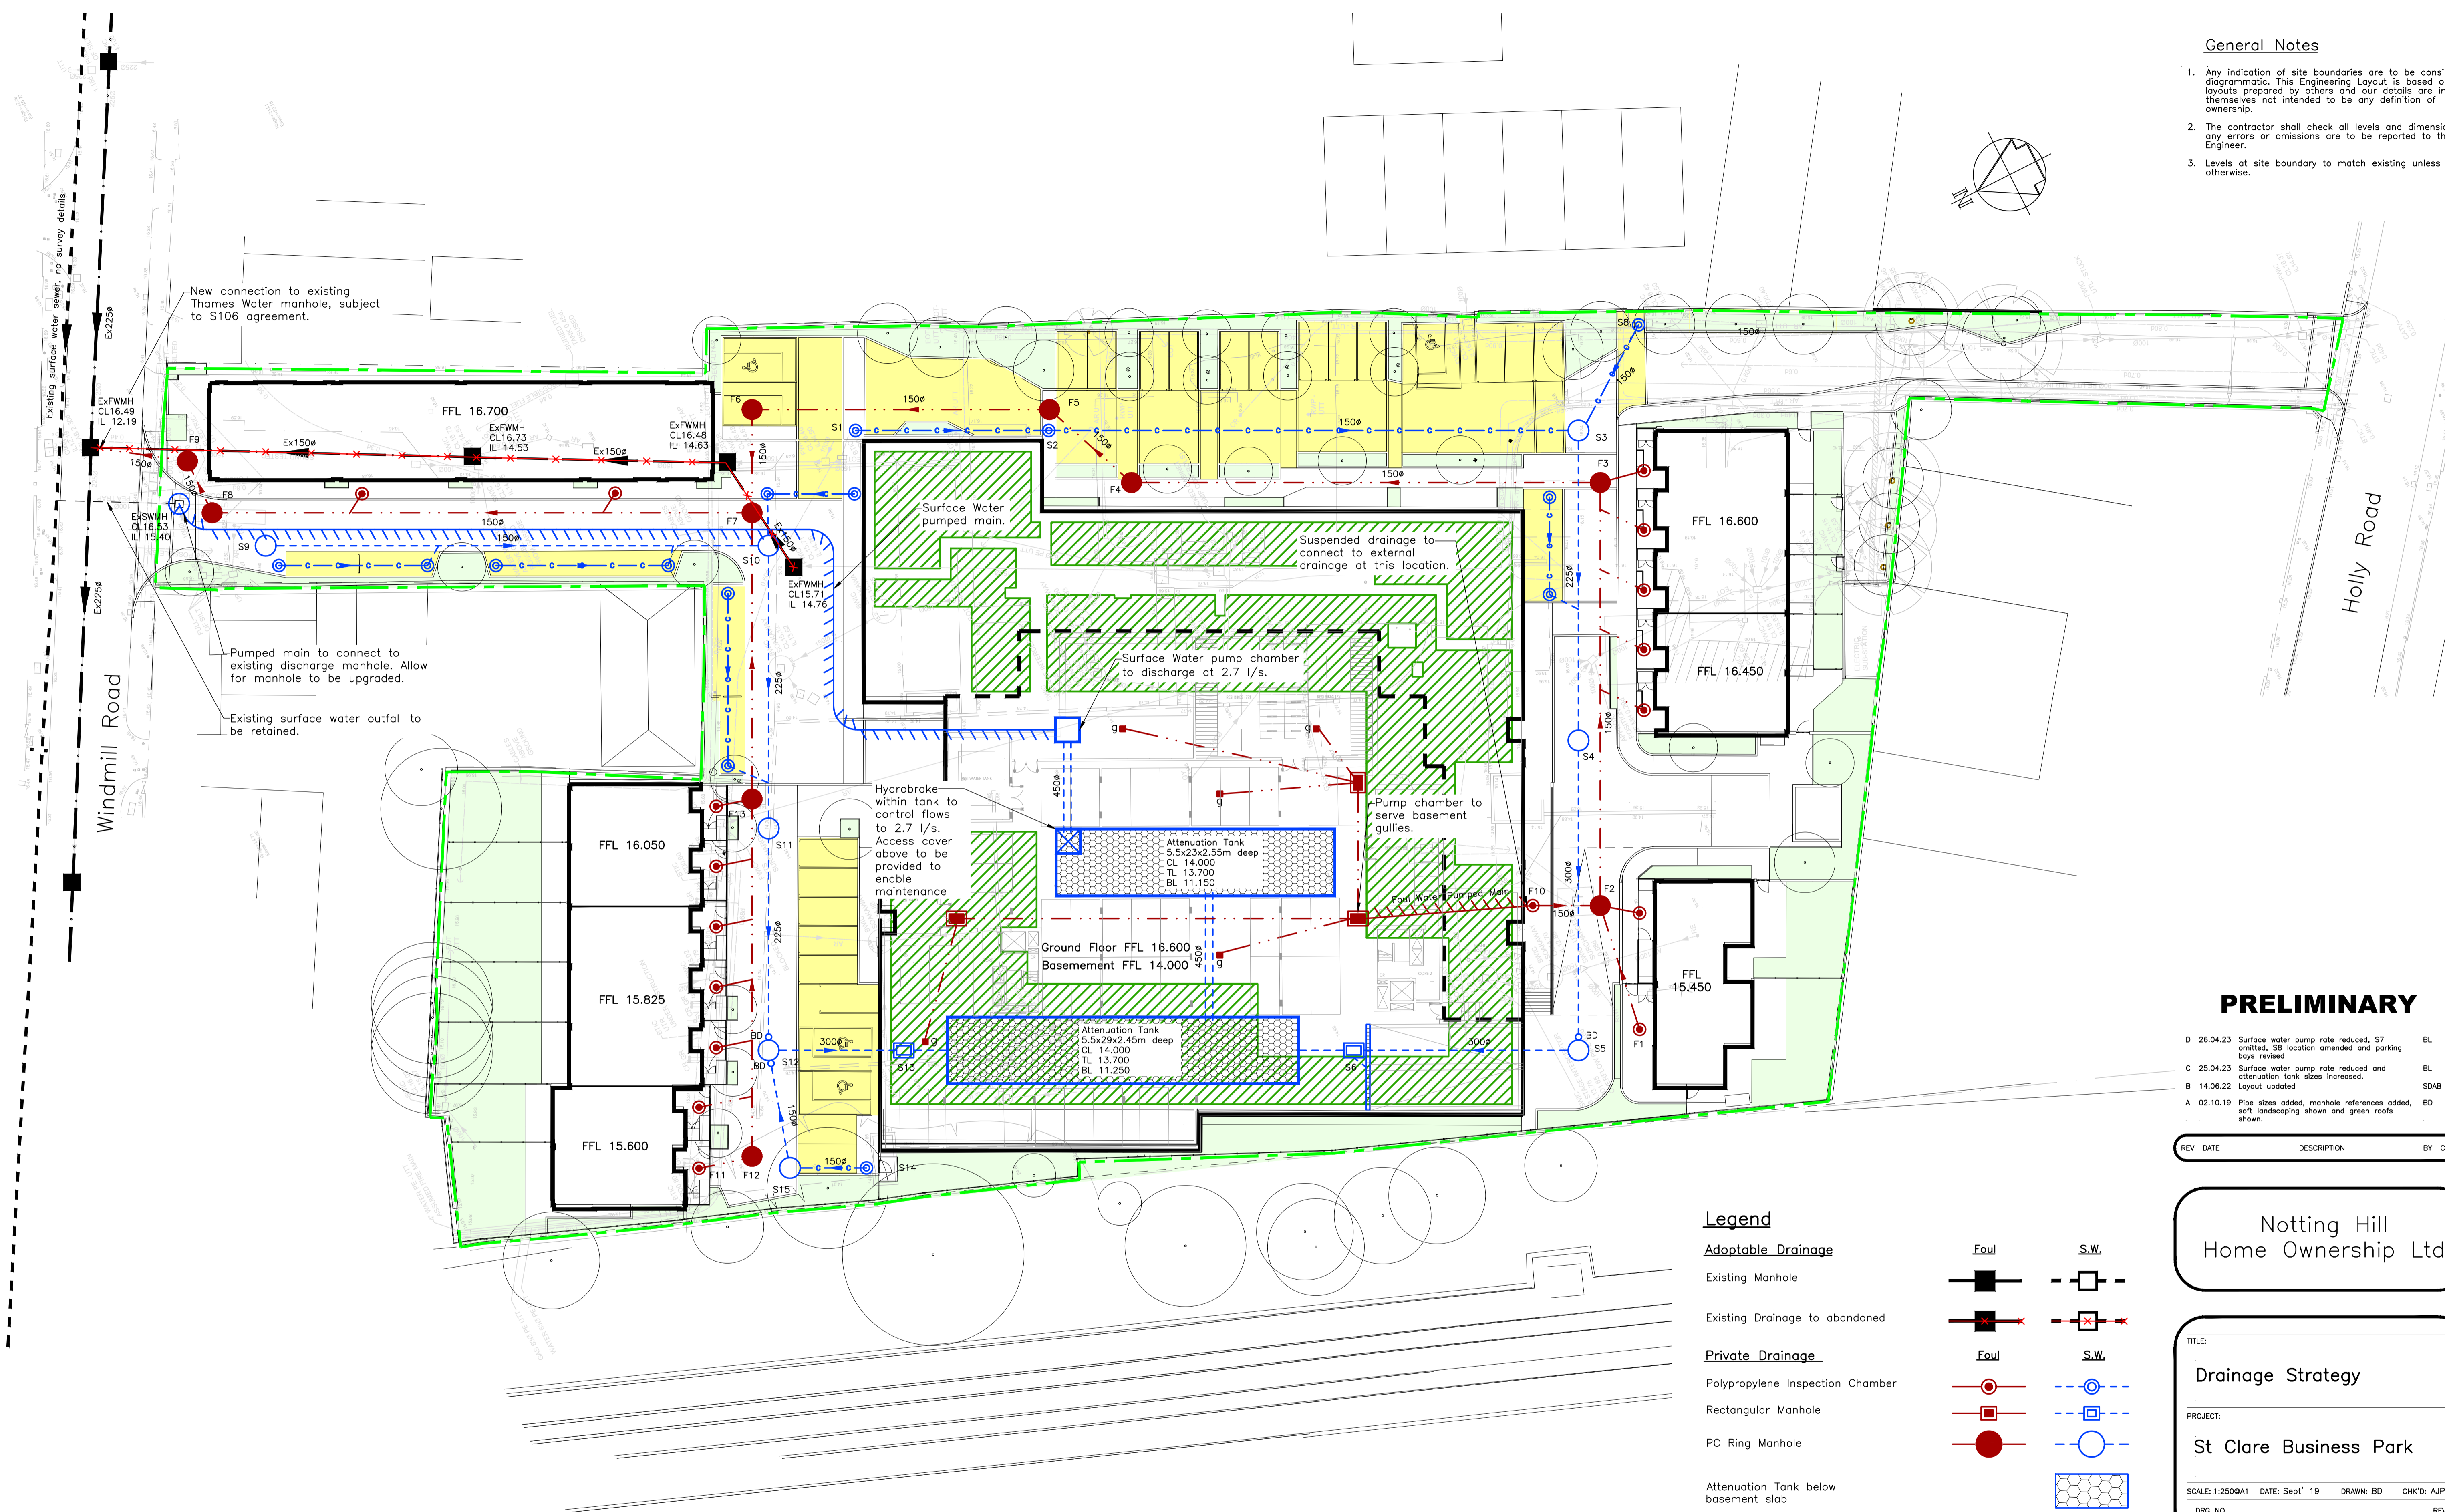

4.6 It is recognised that the basement construction may be located below the groundwater table and potentially forming an obstruction for groundwater flowing to the railway cutting. However the western boundary covers a length of 113m whereas the basement is 53m in length and is located centrally on the western boundary. Consequently the obstruction is only localised within the site.

4.7 With the removal of approximately 7800m² of impermeable surfacing discharging to the onsite soakaways, it is anticipated that the risk of groundwater flooding within the site and in the railway cutting should reduce as a result of the new development.

Appendix A - Drainage Strategy and MicroDrainage Calculations

General Notes

- Any indication of site boundaries to be considered diagrammatic. This Engineering Layout is based on layouts prepared by others and our details are in themselves not intended to be any definition of land ownership.
- The contractor shall check all levels and dimensions, any errors or omissions are to be reported to the Engineer.
- Levels at site boundary to match existing unless noted otherwise.

PRELIMINARY

- | | | |
|------------|--|----------|
| D 26.04.23 | Surface water pump rate reduced, S7 omitted, S8 location amended and parking bays revised. | BL AJP |
| C 25.04.23 | Surface water pump rate reduced and attenuation tank sizes increased. | BL AJP |
| B 14.06.22 | Layout updated. | SDAB AJP |
| A 02.10.19 | Pipe sizes added, manhole references added, soft landscaping shown and green roofs shown. | BD AJP |

TITLE:
Drainage Strategy

PROJECT:
St Clare Business Park

SCALE: 1:250@A1 DATE: Sept' 19 DRAWN: BD CHK'D: AJP
DRG NO. 12153-CIV-200 REV. D

Legend

Adoptable Drainage

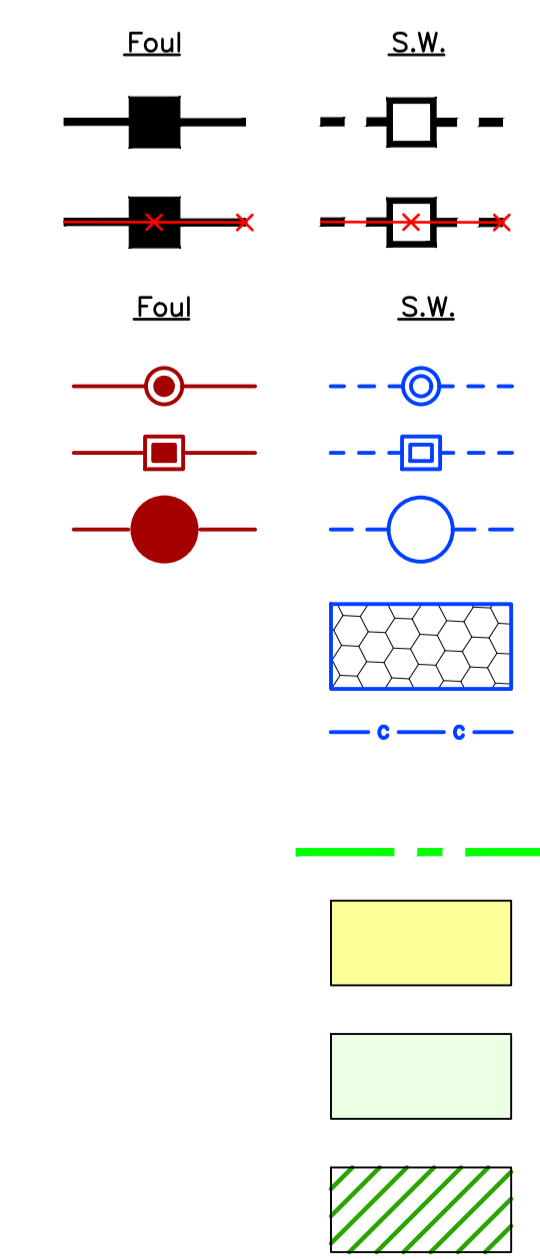

- Existing Manhole
- Existing Drainage to abandoned
- Polypropylene Inspection Chamber
- Rectangular Manhole
- PC Ring Manhole

Private Drainage

- Attenuation Tank below basement slab
- Collector Drain

Other

- Site Boundary
- Permeable Paving
- Soft Landscaping
- Green Roof

Drainage Notes

- Infiltration of surface water is not considered appropriate for this site due to thickness of made ground and depth of groundwater levels.
- Surface water will discharge to the adjacent adopted surface water sewer. Due to site levels relative to the sewer it will be necessary to provide a pumped surface water system. Discharge will be restricted to 5 l/s.
- Surface water attenuation will provided onsite to accommodate a 1 in 100 +40% CC event. This will be provided in below ground attenuation tanks located below Block 1.
